	Requirements for deadlock detection -
1.)	Progress
2.>	Safety

!;	Progress > The method may detect all the deadlocks in the system.
2.)	Safety -> The approach must be capable of detecting all system deadlocks.
,	Apprisaches to detect deadlock in the distributed Sy->
a·)	Centralized Approach > Only one resource is responsible for detecting deadlock
	in the centralized method, and it is
	simple and easy to use. Still, the disadvantages include excessive workload on a single node and single-point failure.
	a single node and single-point failure, making the system less reliable.
b.)	Hierarchical Afbroach - It is the integration
2 1	of both centralized and
	distributed approaches to deadlock detection.
	In this strategy, a single node handles
	a set of selected nodes or clusters of
	In this strategy, a single node handles a set of selected nodes or clusters of nodes that are in charge of deadlock
	detection.
c->	Distributed Approach - In the distributed technique,
	various nodes work to
	detect deadlocks. There is no single point of failure as the workload is equally spread among

An.	Deadlock prevention Techniques-	ART AND ART
	ماد، مثلوبات، مثلوبات، المادة	
	A Deadlock is a situation who of processes are blocked beca	
	processes sare bucker second process is holding a resource waiting for a resource the by some other process:	is and
The Control of the Co	whiting he a resource the	it is held
	La come other brocess:	4 272 6

There are four necessary conditions for a deadlock to happen which are-· Mutual Exclusion · Hold & wait · No preemption · Circular Wait So, the above four conditions are necessary for a deadlock to occur, if any one of the above four conditions is prevented, we can prevent a Deadlock to occur. There are 2 ways to prevent deadlock in a distributed → Ordered Request → Collective Request a) Ordered Request > In this Deadlock Prevention method, each resource type is assigned a certain level to maintain a resource request policy for a process. This is known as the Resource Allocation policy. For each Resource, a global level number is assigned to impose ordering of all resource types. While requesting for a resource, a Process has to make sure that it does not request for a resource whose level order is lower than the

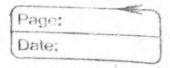

highest - level order resource it currently holds. It can only request resources higher than the highest level resources, held by the process. Ex > There are 10 resources from level 1+010, and 10 is the highest level order resource. If a Process currently has resources 5 and 8, it can't request a resources to a level or request a resource below 8, it can only request resources 9 and 10. This Method makes sure that the circular wait condition is not reached and if one of the deadlock conditions is denied, the deadlock will be prevented. b.) Collective Request -> This method prevents the condition by using any of the following Resource Allocation Policies-This Resource Allocation Policy ensures that a Process requests for all the required resources before the execution of the process. If any of the required resources are not available, the request is not granted.

Here, while requesting any resource, the process should not hold any resources. Que write short notes on a) Path pushing Algorithm > Path - pushing algorithms detect distributed deadlorks by keeping an explicit global WFC . The main concept is to create a global WFC for each distributed system site. When a site in this class of algorithms performs a deadlock computation, it sends its local WFa to all neighboring sites. The term path-pushing algorithm was led to peaken the sending around the paths of global Wfa. b.) Edge-chasing Algorithm > An edge-chasing method verifies a cycle in a distributed graph structure by sending special messages called probes along the graph's edges. These probing messages are messages. If a site receives the matching probe that it previously transmitted, it can cancel the formation of the cycle

94. What do you understand by agreement protocol? Also discuss its application. dut. When the system is pree from failures, an agreement can easily be reached among the processors. However, when the system is prone to failure this method does not work. This is because faulty processors can send conflicting values to other processors preventing them from reaching an agreement. In the presence of faults, processors must exchange their values with other processors and processors several times to isolate the effects of faulty processors. I processor refines its value as it learns of the values of other processors. This entire process of reaching an agreement is called an agreement protocol. Applications of Agreement Protocol > 1) Fault - Tolerant clock Synchronization a.) Distributed Systems require physical clocks
to synchronized:
b.) Physical clocks have drift problem:
c.) Agreement Protocols may help to reach
a common clock value.

	agreement problem should meet the follow	ng
	objectives-	
1)	Agreement - all non faulty processors agree on the same value.	

2) Validity > # the source processor is nonfaulty, then the common agreed upon value by all nonfaulty processors should be the initial value of the source. b.) The consensus Problem > In the consenues broadcasts its initial value to all other processors. Initial values of the processors may be différent. A protocol for reaching consensus should meet the following conditions. 1.) Agreement -> All nonfaulty processor agree on the same single value. 2.) Validity -> If the initial value of every nonfaulty processor is v, then the agreed upon common value by all non faulty processor must be v. C.) The Interactive Consistency Problem > In the interactive consistency problem, every processor broadcasts its initial value to all other processors. The initial value of the processors may be different following conditions must satisfy -
